Abstract

This paper evaluates whether the Philippines will be able to halve the incidence of poverty between 1990 and 2015. Using the concept of exit time and household-level data, we found that the Philippines will be unlikely to do so.

1. Introduction

The international development objectives have converged to reduce poverty in the world since the signing of the Millennium Declaration in September 2000 (United Nations, 2000). The Millennium Development Goals (MDGs) is a concise set of goals, numerical targets and quantifiable indicators to assess the progress of poverty reduction in the whole world specified in the Millennium Declaration. In the Philippines, poverty reduction has been a top priority of its government since 1986.¹ This study aims to assess the progress of the Philippines in reducing poverty using the MDGs as the benchmark. Our analysis focuses on the assessment of progress with respect to Goal 1, i.e., eradicate extreme poverty and hunger and, more specifically, Target 1, i.e., to halve the proportion of people living on less than a dollar a day between 1990 and 2015.

While Besley and Burgess (2003) used cross-country data to evaluate the progress on Target 1 at the global level, no previous attempts have been done to evaluate the progress of poverty reduction in the Philippines using Target 1 as a standard. We incorporated the interprovincial price variations in the US\$1.08 poverty line because such price differences can be considerable in a large and poorly integrated economy such as the Philippines. First, we estimate the internationally comparable poverty line for the each province by using the provincial-level price information. Second, by applying the concept of exit time developed by Kanbur (1987) and Morduch (1998) to the household-level data from the Family Income and Expenditure Surveys (FIES), we made a quantitative assessment of whether the Philippines can achieve Target 1.

¹The Aquino administration (1986-92) had the Comprehensive Agrarian Reform Program as the centerpiece of its anti-poverty program; the Social Reform Agenda for the Ramos administration (1992-98); the “*Lingap Para sa Mahirap*” (looking after the poor) for the Estrada administration (1998-2001); and the “*Kapit-bisig Laban sa Kahirapan*” (linking arms against poverty) for the Arroyo (2001-) administration.

2. Provincial poverty line

The domestic poverty line constructed by the National Statistical Coordination Board (NSCB) of the Philippine government was the most commonly used poverty line. Target 1, on the other hand, was set on the international poverty line, which was pegged at US\$1.08 per capita per day. The use of the consumption-based purchasing power parity (PPP) exchange rate has been generally acceptable to convert the US\$1.08 poverty line into its local currency equivalent (Chen and Ravallion, 2004). We believe, however, that the PPP has to be adjusted to incorporate interprovincial price variations in order to make a more accurate assessment of the provincial poverty situations. Thus, we constructed a provincial-specific PPP adjusted for interprovincial price variations. The PPP for province j in the Philippines in year t is defined as

$$(1) \quad \frac{P_{j,t}^{Ph}}{P_{1993}^{US}},$$

where $P_{j,t}^{Ph}$ is the overall price level in province j and P_{1993}^{US} is the aggregate price level in the US in the benchmark year, 1993. The provincial PPP in Eq. (1) can be represented as a product of the ratio of the provincial-specific price level to the national price level (term A), consumer price index (CPI) in the Philippines (term B), and the country-level PPP in 1993 (term C)

$$(2) \quad \underbrace{\frac{P_{j,t}^{Ph}}{P_{1993}^{US}}}_{\text{Provincial PPP}} = \underbrace{\frac{P_{j,t}^{Ph}}{P_t^{Ph}}}_{\substack{(A) \\ \text{Relative} \\ \text{price} \\ \text{(Term A)}}} \times \underbrace{\frac{P_t^{Ph}}{P_{1993}^{Ph}}}_{\substack{(B) \\ \text{CPI in} \\ \text{the Philippines} \\ \text{(Term B)}}} \times \underbrace{\frac{P_{1993}^{Ph}}{P_{1993}^{US}}}_{\substack{(C) \\ \text{Benchmark} \\ \text{PPP} \\ \text{(Term C)}}},$$

where P_t^{Ph} is the overall price level in the Philippines.² We computed the provincial relative price (term A) in Eq. (2) using a two-step procedure. In the first stage, we utilized the detailed provincial-level individual commodity prices collected by the National Statistics Office (NSO) to calculate the benchmark relative prices for each province. More specifically, for each province, we collected the 2003 price information on rice as a major staple, poultry meat as source of protein, and electricity as a non-food expenditure item, to construct the benchmark price. In the second stage, we utilized the provincial- and national-level CPI to compute the relative prices for other years.

Term B in Eq. (2) was computed using the CPI from the International Financial Statistics of the International Monetary Fund. The benchmark PPP in term C was simply the 1993 consumption-based PPP taken from the Penn World Tables 5.7. Note that this is also the benchmark PPP used by Chen and Ravallion (2004). The monthly value of the US\$1.08 per capita per day corresponds to the provincial PPP in Eq. (2) multiplied by 32.74.

We compared our provincial poverty lines with the domestic provincial poverty lines calculated by the NSCB and with the poverty lines based on the real expenditure calculated by Balisacan (2003).³ A simple OLS regression of our poverty line with that of the NSCB showed a slope of 0.56 and, in the case of Balisacan (2003), a slope of 0.17. Thus, our poverty line appears to have reasonably captured the interprovincial price variations.

We did our calculations on the provincial incidence of poverty using the expenditure data from the FIES in 1985, 1988, 1991, 1994, 1997, and 2000.⁴ In accordance to Target 1, our poverty incidence is at the level of individual members of the households. Table 1 shows an overall reduction in poverty from 1985 to 2000. Such reduction was particularly remarkable in

²A more detailed estimation procedure can be found in Sawada and Estudillo (2005).

³The NSCB domestic poverty lines were calculated using the prevailing domestic prices of a basket of commodities a typical poor consumed. Balisacan's (2003) poverty line was calculated by deflating the nominal expenditure by the true cost of living index, which is defined for fixed reference prices and reference household characteristics.

⁴Estimates of the national and provincial US\$1.08 per capita per day poverty lines and the corresponding poverty incidence indicators are available from the authors upon request.

provinces with higher initial levels of poverty in 1985 such as those located in Bicol Region (e.g., Albay, Catanduanes, and Sorsogon), Eastern Visayas (e.g., Siquijor, Leyte, Southern Samar, Southern Leyte, and Western Samar), and Northern Mindanao (e.g., Misamis Occidental and Misamis Oriental). Provinces with lower incidence of poverty from 1985 were those located closer to Manila such as provinces in the Southern Tagalog Region in the CALABARZON area (e.g., Laguna, Rizal, Batangas and Cavite) and Central Luzon Region (e.g., Bulacan, Bataan, Pampanga, and Nueva Ecija). Moreover, these provinces experienced higher growth rates of household income as industries tended to be set up in these provinces because of its proximity to Manila, better communication and telecommunication facilities, and relatively more educated labor force.

3. The role of economic growth in achieving the Target 1

Using the PPP-based provincial poverty line, we applied the concept of exit time developed by Kanbur (1987) and Morduch (1998) to quantify the income growth rate necessary to achieve Target 1. Exit time, t_i , is defined as the time an individual i with expenditure y_i below the poverty line, z , will exit the poverty situation,

$$(3) \quad t_i = \frac{\ln(z) - \ln(y_i)}{\ln(1 + g)}$$

where g is the growth rate of real per capita expenditure of individual i .

Let μ_i^p represents the median real per capita expenditure of an individual poor in province p in year t and t_{μ}^p represent the exit time of the median poor individual. Since the MDGs require t_{μ}^p to be equal to 25 years, i.e., from 1990 to 2015, we can easily compute the required real per capita expenditure growth rate of the median poor, g^p . Since the FIES is not available in 1990,

we utilized the data on 16,971 households in the 1988 FIES to quantify the growth that is necessary to halve the incidence of poverty between 1988 and 2015. The necessary growth rate of real per capita expenditure is represented by

$$(4) \quad g^p = \exp\left[\frac{\ln(z) - \ln(\mu_{1988}^p)}{27}\right] - 1.$$

This can be considered as a *lower bound* of the necessary growth rate of real per capita expenditure to achieve Target 1 between 1990 and 2015.

The required growth rate for each province varies from the lowest of 0.14% per year (in Cavite) to the highest of 1.75% per year (in Romblon).⁵ According to Table 1, the Philippines as a whole will not be able to comply with Target 1 as the real per capita expenditure growth rate of the median poor is only 0.23% per annum. The real per capita expenditure of the median poor needs to grow by an additional 0.55% point per annum in order to comply. Out of the 72 provinces, only 15 (of which 10 are well within reach from Manila) will be able to comply with Target 1.⁶

Figure 2 shows the kernel density distributions of provincial-level actual real per capita expenditure growth rate and the required growth rate to achieve Target 1. A mere eye-ball test of the first-order stochastic dominance shows that the distribution of the actual growth rate was dominated by the distribution of the required growth rate. Indeed, the two-sample Kolmogorov-Smirnov test rejected overwhelmingly the hypothesis on equality of these two distribution functions; the KS test statistic for equality of these CDFs is 0.500 with a P value less than 0.01. Figure 2 is a kernel density function of the growth rate gap, which is defined as the difference between the necessary growth rate to achieve Target 1 and the actual growth rate. It is interesting

⁵The provincial-wise necessary growth rates are available from the authors upon request.

⁶We eliminated six provinces because these provinces were not yet established in 1988 or were not represented in the FIES.

to find a symmetric distribution but obviously a majority of the provinces took a negative value. Hence, we may conclude that, at the national level, the Philippines will not be able to achieve Target 1. It is important to mention that Chen and Ravallion (2004) and Besley and Burgess (2003) assessed that East Asia as a whole will be most likely to comply with Target 1 so that the Philippines appears to be an exception.

4. Conclusions

This paper aimed to assess the performance of the Philippines with respect to Target 1 using the US\$1.08 per capita per day poverty line adjusted for interprovincial price differences. Our evidences showed that the Philippines as a whole will not be able to comply with Target 1, although 15 of its provinces will be able to do so. These provinces were closer to Manila, characterized by higher growth rates of individual per capita real expenditure, and had lower incidence of poverty in 1988. This suggests the importance of policy interventions that mitigate the emergence of regional disparity in achieving the MDGs. Balisacan and Fuwa (2003) suggested political competitiveness that may lead to income convergence across provinces.
